What is XML?

EXtensible **M**arkup **L**anguage (**XML**) is a markup language that is designed to store and transport data in a format that is both human-readable and machine-readable.

- XML stands for eXtensible Markup Language.
- XML is a markup language much like HTML.
- XML was designed to store and transport data.
- ML was designed to be self-descriptive.
- ML is widely used for data storage, exchange, and configuration purposes.
- It provides a platform-independent and standardized way to represent structured data, making it easier for different systems to exchange and interpret information.

HTML VS XML

Main difference between HTML and XML:

- **HTML**: shows how data looks (presentation).
- **XML**: shows what data means (structure + content).
- In XML, you can create your own tags, while HTML uses predefined ones.

XML Simplifies Things:

- XML simplifies data sharing.
- XML simplifies data transport.
- XML simplifies platform changes.
- XML simplifies data availability.
- XML + XSLT → New Format (html, PDF,.. etc).
